Pyrite or Iron Pyrite is a mineral with the formula FeS_2 (chemical name: iron disulphide). The mineral is an important iron and sulfur ester. It often forms well-formed (euhedric) crystals in the shape of a cube with characteristic striations and with a golden shine. It is also called tinsel or crazy men's gold (from the English fool's gold) because it sometimes became gold. The name cat's gold is sometimes also used incorrectly, but it is a yellow mica or resin. Because pyrite occurs to a large extent, this can cause the illusion of great wealth. However, pyrite is not worth much (although it can be sold). It is found in conjunction with other sulfur-containing minerals, but also with oxides, quartz veins, carbon deposition rocks and fossil substitutes. The most beautiful Pyrite is from Peru, China (rough mineral pieces) and the U.S.A. Pyrite Suns (Dollars)
